Recursion

Instructor: W. M. Farmer

Revised: 4 October 2001

1

Recursion Example: Factorial

```
MODULE Factorial;
IMPORT Out;

PROCEDURE FactRec(x: LONGINT): LONGINT;
  (* Computes the factorial function using (nontail) recursion. *)
  BEGIN
    IF x < 0 THEN
      Out.String("Input must be nonnegative (ignore output).");
      RETURN -1;
    ELSIF x = 0 THEN
      RETURN 1;
    ELSE
      RETURN FactRec(x - 1) * x;
    END;
  END FactRec;
END Factorial.
```

3

What is Recursion?

- **Recursion** is a method of defining something in terms of itself
 - One of the most fundamental ideas of computing
 - An alternative to iteration (loops)
 - Can make some programs easier to describe, write, and prove correct
- Both procedures and data structures can be defined by recursion
 - A set of procedures or data structures can be defined by **mutual recursion**

2

Semantics

- A recursive procedure can be understood as:
 - A definition of a procedure with an infinite body
 - An operational definition (little machine)
 - An implicit definition of a procedure that satisfies a certain property
- The use of recursion requires care and understanding
 - Recursive definitions can be nonsensical (i.e., nonterminating)
 - Sloppy use of recursion can lead to total confusion

4

Implementation

- Recursive procedures are usually implemented using a **call stack**
 - The stack contains one **frame** per procedure call
 - The nesting depth of recursive calls does not need to be calculated before execution
- If the nesting depth of recursive calls is infinite, the procedure will run until the stack space is exhausted

5

Tail Recursion

- A procedure is **tail recursive** if nothing is left to do after each recursive call in the procedure body
- Tail recursive procedures can be made to execute in constant space:
 - In some programming languages, e.g., Scheme, the compiler ensures that tail recursive procedures execute in constant space
 - In other programming languages, tail recursive procedures can be redefined using iteration (which executes in constant space)

7

Quality Issues

- **Termination** is shown using a **well-founded ordering**
 - E.g., a strictly decreasing natural number value
- **Correctness** can be proved using induction
- **Efficiency**
 - In some cases, recursion can be highly inefficient in the use of space
 - In some cases, recursion can be executed in constant space

6

Tail Recursion Example: Factorial

```
MODULE Factorial;
IMPORT Out;

PROCEDURE FactTailRec*(x: LONGINT): LONGINT;
  (* Computes the factorial function using tail recursion. *)
  BEGIN
    RETURN FactTailRecAux(x,1);
  END FactTailRec;

PROCEDURE FactTailRecAux(x: LONGINT; accum: LONGINT): LONGINT;
  BEGIN
    IF x < 0 THEN
      Out.String("Input must be nonnegative (ignore output).");
      RETURN -1;
    ELSIF x = 0 THEN
      RETURN accum;
    ELSE
      RETURN FactTailRecAux(x - 1, accum * x);
    END;
  END FactTailRecAux;

END Factorial.
```

8

The BESTT Logic

- BESTT is a Basic Extended Simple Type Theory
 - Higher-order predicate logic
 - Includes type variables, lambda notation, and a definite description operator
 - Has support for reasoning with tuples, lists, and sets
- Several of the principal computer theorem systems are based on simple type theory: HOL, IMPS, PVS, TPS
- Reference:

9

Trees Example: Planning Language 1

- Data Structure Type:

```
Tree = record
  atomic: Boolean;  (* true if integer; false if pair *)
  int: Integer;
  left: Tree;
  right: Tree;
end Tree;
```
- Constructors:

```
procedure MakeIntegerTree(i: Integer): Tree;
  return (true, i, null, null);
end MakeIntegerTree;

procedure MakePairTree(t1,t2: Tree): Tree;
  return (false, null, t1, t2);
end MakePairTree;
```

11

Trees Example: Mathematical

- The set Tree of **binary integer trees** is defined recursively by the following statements:
 1. If $x \in \mathbf{Z}$, then $x \in \text{Tree}$.
 2. If $x, y \in \text{Tree}$, then $(x, y) \in \text{Tree}$.
- The following tree functions are defined recursively as follows:

$$\forall t: \text{Tree}. \text{sum}(t) = \text{if}(t \in \mathbf{Z},$$

$$\quad t,$$

$$\quad \text{sum}(\text{fst}(t)) + \text{sum}(\text{snd}(t)))$$

$$\forall t: \text{Tree}. \text{ht}(t) = \text{if}(t \in \mathbf{Z},$$

$$\quad 1,$$

$$\quad 1 + \text{max}(\text{ht}(\text{fst}(t)), \text{ht}(\text{snd}(t))))$$

10

Trees Example: Planning Language 2

- Selectors:

```
procedure IsIntegerTree(t: tree): Boolean;
  ((t.atomic -> return true) |
   ("t.atomic -> return false))
end IsIntegerTree;

procedure IsPairTree(t: tree): Boolean;
  return ~IsIntegerTree(t);
end IsPairTree;

procedure GetInteger(t: tree): Integer;
  ((IsIntegerTree(t) -> return t.int) |
   (IsPairTree(t) -> abort))
end GetInteger;
```

12

Trees Example: Planning Language 3

```
procedure GetLeftTree(t: tree): Tree;
  ((IsIntegerTree(t) -> abort) |
   (IsPairTree(t) -> return t.left))
end GetLeftTree;

procedure GetRightTree(t: tree): Tree;
  ((IsIntegerTree(t) -> abort) |
   (IsPairTree(t) -> return t.right))
end GetRightTree;
```

Trees Example: Planning Language 5

```
• Tree procedures:

procedure Sum(t: Tree): Integer;
  ((IsIntegerTree(t) -> return GetInteger(t)) |
   (IsPairTree(t) -> return Sum(GetLeftTree(t)) +
    Sum(GetRightTree(t))))
end Sum;

procedure Height(t: Tree): Integer;
  ((IsIntegerTree(t) -> return 1) |
   (IsPairTree(t) ->
    return 1 + Max(Height(GetLeftTree(t)),
                   Height(GetRightTree(t)))))
end Height;
```

Trees Example: Planning Language 4

```
• Mutators:

procedure SetInteger(t: tree; i: Integer);
  ((IsIntegerTree(t) -> t.int := i |
   (IsPairTree(t) -> abort))
end SetInteger;

procedure SetLeftTree(t: tree; t1: Tree);
  ((IsIntegerTree(t) -> abort) |
   (IsPairTree(t) -> t.left := t1))
end SetLeftTree;

procedure SetRightTree(t: tree; t2: Tree);
  ((IsIntegerTree(t) -> abort) |
   (IsPairTree(t) -> t.right := t2))
end SetRightTree;
```

Trees Example: Oberon 1

```
MODULE Trees;

IMPORT Out;

(* Data structure type: *)
TYPE

  Tree* = POINTER TO TreeRec;

  TreeRec = RECORD
    atomic: BOOLEAN; (* True if integer; false if pair *)
    int: INTEGER;
    left: Tree;
    right: Tree;
  END;
```

Trees Example: Oberon 2

```
(* Constructors: *)

PROCEDURE MakeIntegerTree*(i: INTEGER): Tree;
VAR t: Tree;
BEGIN
  NEW(t);
  t^.atomic := TRUE;
  t^.int := i;
  t^.left := NIL; (* Denotes null tree *)
  t^.right := NIL; (* Denotes null tree *)
  RETURN t;
END MakeIntegerTree;

PROCEDURE MakePairTree*(t1,t2: Tree): Tree;
VAR t: Tree;
BEGIN
  NEW(t);
  t^.atomic := FALSE;
  t^.int := 0; (* Denotes null integer *)
  t^.left := t1;
  t^.right := t2;
  RETURN t;
END MakePairTree;
```

17

Trees Example: Oberon 4

```
PROCEDURE GetLeftTree*(t: Tree): Tree;
BEGIN
  IF IsIntegerTree(t) THEN
    Out.String("Error in Trees.GetLeftTree:
               argument is an integer tree.");
    HALT(20); (* Abort program *)
  ELSE
    RETURN t^.left;
  END;
END GetLeftTree;

PROCEDURE GetRightTree*(t: Tree): Tree;
BEGIN
  IF IsIntegerTree(t) THEN
    Out.String("Error in Trees.GetRightTree:
               argument is an integer tree.");
    HALT(20); (* Abort program *)
  ELSE
    RETURN t^.right;
  END;
END GetRightTree;
```

19

Trees Example: Oberon 3

```
(* Selectors: *)

PROCEDURE IsIntegerTree*(t: Tree): BOOLEAN;
BEGIN
  RETURN t^.atomic;
END IsIntegerTree;

PROCEDURE IsPairTree*(t: Tree): BOOLEAN;
BEGIN
  RETURN ~IsIntegerTree(t);
END IsPairTree;

PROCEDURE GetInteger*(t: Tree): INTEGER;
BEGIN
  IF IsIntegerTree(t) THEN
    RETURN t^.int;
  ELSE
    Out.String("Error in Trees.GetInteger:
               argument is a pair tree.");
    HALT(20); (* Abort program *)
  END;
END GetInteger;
```

18

Trees Example: Oberon 5

```
(* Mutators: *)

PROCEDURE SetInteger*(t: Tree; i: INTEGER);
BEGIN
  IF IsIntegerTree(t) THEN
    t^.int := i;
  ELSE
    Out.String("Error in Trees.SetInteger:
               argument is a pair tree.");
    HALT(20); (* Abort program *)
  END;
END SetInteger;

PROCEDURE SetLeftTree*(t: Tree; t1: Tree);
BEGIN
  IF IsIntegerTree(t) THEN
    Out.String("Error in Trees.SetInteger:
               argument is an integer tree.");
    HALT(20); (* Abort program *)
  ELSE
    t^.left := t1;
  END;
END SetLeftTree;
```

20

Trees Example: Oberon 6

```
PROCEDURE SetRightTree(t: Tree; t2: Tree);
BEGIN
  IF IsIntegerTree(t) THEN
    Out.String("Error in Trees.SetInteger:
               argument is an integer tree.");
  ELSE
    HALT(20); (* Abort program *)
  END;
  t.right := t2;
END SetRightTree;

(* Tree Procedures: *)

PROCEDURE Sum*(t: Tree): INTEGER;
BEGIN
  IF IsIntegerTree(t) THEN
    RETURN GetInteger(t);
  ELSE
    RETURN Sum(GetLeftTree(t)) + Sum(GetRightTree(t));
  END;
END Sum;

END Trees.
```

Pattern Matching: New Problem

- Input:
dat: Array n of Character (data string)
pat: Array p of Character (pattern string)
mat: Array n of Boolean (match array)
 s : $\mathbf{N}$ (start of potential match)
 m : $\mathbf{N}$ (number of matched characters)
- Output:
mat: Array n of Boolean (match array)
- Invariant I :
 $(m < p) \wedge$
 $(\forall i: \mathbf{N}. 0 \leq i < \min(s, n) \supset \text{mat}[i] \equiv \text{match-at}(\text{pat}, \text{dat}, i)) \wedge$
 $(\forall j: \mathbf{N}. 0 \leq j < m \supset \text{pat}[j] = \text{dat}[s + j])$

Pattern Matching: Problem

- Input:
dat: Array n of Character (data string)
pat: Array p of Character (pattern string)
- Output:
mat: Array n of Boolean (match array)
- Definition of match-at:
match-at(pat, dat, i) $\equiv$
 $\forall j: \mathbf{N}. 0 \leq j < p \supset \text{pat}[j] = \text{dat}[i + j]$
- Specification S :
 $\forall i: \mathbf{N}. 0 \leq i < n \supset \text{mat}[i] \equiv \text{match-at}(\text{pat}, \text{dat}, i)$

Pattern Matching: match

```
procedure match(pat: Array p of Character;
               dat: Array n of Character): Array n of Boolean;
var mat: Array n of Boolean;

(* initialize mat *)
var i: Integer;
i := 0;
it
  ((i < n -> mat[i] := false; go) |
   (i >= n -> stop))
ti

return match-aux(pat, dat, mat, 0, 0);
end match;
```

Pattern Matching: match-aux

```
procedure match-aux(pat: Array p of Character;  
  dat: Array n of Character;  
  mat: Array n of Boolean;  
  s: Natural;  
  m: Natural): Array n of Boolean;  
  ((s + p > n -> return mat) | (* dat is exhausted *)  
  (s + p <= n ->  
    (pat[m] = dat[s+m] -> (* next char is matched *)  
      m := m + 1;  
      ((m = p ->  
        mat[s] := true; (* pat is matched *)  
        s := s + advance(pat,m);  
        m := 0) |  
        (~ (m = p) -> skip))) | (* pat is not (yet) matched *)  
    (~ (pat[m]=dat[s+m]) -> (* next char is not matched *)  
      (* mat[s] remains false *)  
      s := s + advance(pat,m);  
      m := 0)))  
  return match-aux(pat,dat,mat,s,m)  
end match-aux;
```

Pattern Matching: Conclusions

- 1. The recursion terminates since (s, m) strictly increases in lexicographic order until $s + m \geq n$
- 2. I is an invariant of the recursion:
 - I is true when match calls match-aux
 - I is true each time match-aux calls itselfHence, I is true when match-aux terminates
- 3. Therefore, match satisfies S (provided advance is correct)
 - Note: advance is correct, but not necessarily optimal, if it always returns 1
