An Approach to Process Algebra using IMPS

F. Javier Thayer *

April 11, 1995

Abstract

In this paper we develop a formal mathematical model for processes, along the lines of Communicating Sequential Processes (CSP). Our development is completely general and is capable of dealing with time. Rather than building semantic models on a traditional trace-based failures model, we replace the set of traces by the set of elements of a monoid. In the case of untimed CSP, this monoid is taken to be the set of all event sequences under concatenation; mathematically this is the free monoid generated by the event alphabet. For timed CSP, one natural monoid that may be considered is the free monoid generated by the set of atomic events together with the wait operators $W(t)$ for $t$ a real number with the relations $W(t + s) = W(t)W(s)$.

1 Introduction

In this paper we develop a new approach to process algebra and CSP. One goal of the paper is to provide a foundation for subsequent work in process specification, and to this end, the development has been done entirely using the IMPS system. For an overview of the IMPS system, see [6, 7]. Moreover, we have departed from the usual formulations in which external behaviors are modeled as sequences of events called traces. In the following presentation, we have adopted a mathematically more satisfying and more general approach which replaces the set of traces by the set of elements of a monoid.

We have two main examples in mind:

1. In the case of untimed CSP, this monoid is taken to be the set of all event sequences under concatenation; mathematically, this is the free monoid generated by the event alphabet.

2. For timed CSP, one natural monoid that may be considered is the free monoid generated by the set of atomic events together with the wait operators \( W(t) \) for \( t \) a real number with the relations \( W(t+s) = W(t)W(s) \).

In this approach to process semantics, in general there may be no “atomic” events, that is, events which are not themselves non-trivial products. Indeed, actions have to be defined as certain classes of monoid elements under an equivalence relation \( \equiv \), where \( a \equiv b \) for monoid elements \( a, b \) means that either

- Both \( a \) and \( b \) are the identity of the monoid, or
- \( a, b \) have a nontrivial common prefix

The set of actions consist of “germs” of monoid elements. If we think of monoid elements as being the external interactions of a process, the germ of an element is a mathematical representation of the process's initial behavior. For example, in the case of untimed CSP, the germ is the first action of the process.

In order to relate this approach to the myriad of existing approaches to process theory, we have developed a theory of mathematical structure which captures some of the formalism of process transition. We refer to this structure as a Monoid Transition System (MTS). This extends the concept of
a Labelled Transition System developed by Hennessey, Olderog and others. Following Matthew Hennessey’s approach we define various kinds of possible testing semantics and explore the relations between the various notions. One version of the testing semantics associates to each element of an MTS a function on the set of monoid elements. This function is the set of failures of the process.

We then consider the set of failures, show that in a natural way it is an ultrametric space, and prove its completeness. The relevance of this result is that it mathematically justifies recursion as a means of process definition. Indeed, if $f$ is a contractive functional on the space of failures, then there is a unique $p$ such that $p = f(p)$.

All of the mathematics that is used implicitly or explicitly in this paper has been developed using IMPS, and, in particular, all the proofs have been machine-checked. The proofs themselves are represented as runnable scripts, but for lack of space in the paper they are not included here, but are publically available along with the IMPS distribution. Some of the preliminary mathematical development is also omitted in this presentation. This includes the theory of metric-space topology up to the Contractive Fixed Point Theorem. For a discussion of this see [5].

This paper does assume a basic knowledge of the IMPS system as described in the manual [7]. In particular, the reader should be forewarned that terms may be undefined and functions may be partial, that is defined on only part of their syntactic domain.

# Preliminaries

We begin with the definition of the theory of a single monoid. A monoid is a set with a single binary, associative operation, and an identity. Notice that in our formalization of a monoid as an IMPS theory, we are also throwing in the real numbers. This gives us the integers for free and allows us to define additional concepts which require the integers, such as sequential products.

**Language 2.1 (monoid-language)**

Embedded language: h-o-real-arithmetic

Base type: $U$

Constants: $e : U$

$** : [U \times U \rightarrow U]$
Component theory: h-o-real-arithmetic
Top level axioms:
associative-law-for-multiplication-for-monoids
\[ \forall z, y, x : U \quad x \cdot y \cdot z = x \cdot y \cdot z. \]
right-multiplicative-identity-for-monoids \[ \forall x : U \quad x \cdot e = x. \]
left-multiplicative-identity-for-monoids \[ \forall x : U \quad e \cdot x = x. \]
anonymous \[ \text{total}(**,[U \times U \rightarrow U]). \]

Figure 1: Components and axioms for monoid-theory

Theory 2.2 (monoid-theory)
Language: monoid-language
Component Theories and Axioms: See Figure 1.

Definition 2.3 (prefix)
Theory: monoid-theory
\[ [m,n : U \mapsto \exists p : U \quad n = m \cdot p]. \]

Notice that if the monoid is a group, the prefix relation is completely trivial, that is, every element is a prefix of every other element. This is in sharp contrast to the monoid of finite sequences over an alphabet in which the prefix relation is antisymmetric.

Theorem 2.4 (prefix-is-transitive)
Theory: monoid-theory
\[ \forall x, y, z : U \quad s. \ t. \quad \text{prefix}(x, y) \land \text{prefix}(y, z), \]
\[ \text{prefix}(x, z). \]

Theorem 2.5 (prefix-is-reflexive)
Theory: monoid-theory
\[ \forall x : U \quad \text{prefix}(x, x). \]

In the case of the monoid of traces, the prefix relation which we abstractly defined corresponds exactly to the usual prefix relation for sequences. Now we define an equivalence relation between monoid elements. Monoid elements \( x, y \) satisfy this relation if either both are equal to the identity element or they have a common initial segment.
**Component theory:** monoid-theory

**Top level axioms:**

**directed-property** \( \forall x, y, z : U \) implication

- conjunction
  - \( \neg(x = e) \)
  - \( \neg(z = e) \)
  - prefix\((x, y)\)
  - prefix\((z, y)\)
- \( \exists u : U \) conjunction
  - \( \neg(u = e) \)
  - prefix\((u, x)\)
  - prefix\((u, z)\).

**no-units** \( \forall x : U \) s. t. prefix\((x, e)\),
\[ x = e. \]

Figure 2: Components and axioms for directed-monoid-theory

**Definition 2.6 (init_eqv)**

Theory: monoid-theory

\[ a, b : U \mapsto \]

disjunction

- \( a = e \land b = e \)
- \( \neg(a = e) \land \neg(b = e) \land (\exists x : U \ \neg(x = e) \land \text{prefix}(x, a) \land \text{prefix}(x, b)) \].

**Theorem 2.7 (directed-monoid-theory)**

Language: the-null-language

Component Theories and Axioms: See Figure 2.

**Theorem 2.8 (init_eqv-reflexive-property)**

Theory: monoid-theory

\( \forall x : U \ \text{init_eqv}(x, x) \).

**Theorem 2.9 (init_eqv-symmetric-property)**

Theory: monoid-theory

\( \forall x, y : U \ \iff \)

- init_eqv\((x, y)\)
- init_eqv\((y, x)\).
Theorem 2.10 (init_eqv-transitive-property)
Theory: directed-monoid-theory
\( \forall x, y, z : U \ s.t. \ init_eqv(x, y) \land init_eqv(y, z), \)
\( init_eqv(x, z). \)

Translation 2.11 (generic-theory-to-directed-monoid)
Source Theory: generic-theory-1
Target Theory: directed-monoid-theory
Sort Pairs: ind_1 \rightarrow U

This translation is a theory interpretation.

We now define a mapping denoted “germ,” which maps the sort \( U \) into equivalence classes of elements of \( U \). Thus for \( m \in U \), \( germ(u) \) is a set of monoid elements. The sort action is then defined to be the range of the germ function. In order for these definitions to make sense, a few preliminary lemmas are needed.

In the following theorem we use the notation \( t \downarrow \) to mean that the term \( t \) is defined.

Theorem 2.12 (Anonymous)
Theory: directed-monoid-theory
\( \text{quotient(init_eqv)} \downarrow \).

Definition 2.13 (germ)
Theory: directed-monoid-theory
\( \text{quotient(init_eqv)} \).

Theorem 2.14 (totality-of-germ)
Theory: directed-monoid-theory
\( \text{total(germ, [U \rightarrow sets[U]])} \).

Theorem 2.15 (germ-equality-condition)
Theory: directed-monoid-theory
\( \forall m, n : U \iff \)
- \( germ(m) = germ(n) \)
- disjunction
  - \( m = e \land n = e \)
  - \( \exists u : U \land \neg(u = e) \land \text{prefix}(u, m) \land \text{prefix}(u, n) \).
**Theorem 2.16 (Anonymous)**
Theory: directed-monoid-theory
nonempty \{run\{germ\}\}.

Having established that the germ function has a non empty range, we can now legitimately define the sort **action**. In IMPS sorts are defined by the predicate which recognizes which elements are elements of that sort. In this case the predicate is membership in the range of the germ function. Note that in the conventional trace framework, atomic actions are also traces whereas, in our approach, there is generally no natural inclusion mapping from actions into traces.

**Sort Definition 2.17 (action)**
Theory: directed-monoid-theory
\[ s : \text{sets}[U] \rightarrow s \in \text{run}\{\text{germ}\} \].

## 3 Monoid Transition Systems

In this section, we construct a model of a set of processes. In traditional formulations of process theory, there is given a basic set of atomic actions (see [10]) which are the building blocks of processes. This set of actions is usually called the **alphabet** of the process. Let us call this set **action**. Moreover, processes \( p, q \) can be related to each other via an observable event \( a \) drawn from the set **action**. We write this ternary relation as follows \( p \xrightarrow{a} q \). This is thought of as the process \( p \) becoming the process \( q \) via an observable event \( a \). This kind of structure is referred to as a *labelled transition system* [8, 9]. It is straightforward (see [8]) to define a derived relation \( \rightarrow \) for triples \( (p, \mu, q) \) where \( p, q \) are processes and \( \mu \) is a sequence of actions.

In the model we construct in this paper, processes are related to each other by *event traces*; the event traces themselves are modeled by a monoid. This extends the concept of a labelled transition system if we regard the set of event sequences as being a monoid under concatenation.

For other different approaches to process algebra, see [3, 4, 11].

**Language 3.1 (language-for-monoid-transition-system)**
Embedded language: **monoid-theory**
Base type: state
Constant: \( \text{act : [state} \times U \times \text{state} \rightarrow *] \)
Figure 3: Components and axioms for monoid-transition-system

Theory 3.2 (monoid-transition-system)
Language: language-for-monoid-transition-system
Component Theories and Axioms: See Figure 3.

We now define acceptance and refusal sets for both transitions and actions.

Definition 3.3 (accepted_transitions)
Theory: monoid-transition-system
\[ [p : \text{state} \rightarrow \{m : \mathcal{U} | \exists q : \text{state} \quad p \xrightarrow{m} q \}] \].

Definition 3.4 (refused_transitions)
Theory: monoid-transition-system
\[ [p : \text{state} \rightarrow \{m : \mathcal{U} | \forall q : \text{state} \quad \neg(p \xrightarrow{m} q)\}] \].

Theorem 3.5 (accepted_transitions-is-prefix-closed)
Theory: monoid-transition-system
\[ \forall p : \text{state}, m, n : \mathcal{U} \quad \text{implication} \]
\[ \bullet \text{conjunction} \]
\[ \circ m \in \text{accepted_transitions}(p) \]
\[ \circ \text{prefix}(n, m) \]
\[ \bullet n \in \text{accepted_transitions}(p) \].

Definition 3.6 (accepted_actions)
Theory: monoid-transition-system
\[ p : \text{state} \mapsto \\
\{ a : \text{action} | \exists m : U \quad \text{conjunction} \\
\quad \bullet \text{germ}(m) = a \\
\quad \bullet m \in \text{accepted_transitions}(p) \} \].

**Definition 3.7 (refused_actions)**
Theory: monoid-transition-system
\[ p : \text{state} \mapsto \\
\{ a : \text{action} | \forall m : U \quad s. t. \quad \text{germ}(m) = a, \\
\quad \neg(m \in \text{accepted_transitions}(p)) \} \].

**Theorem 3.8 (refused_actions-is-total)**
Theory: monoid-transition-system
total(refused_actions, [state \to sets[action]]).

**Lemma 3.9 (accepted_actions-is-complement-of-refused_actions)**
Theory: monoid-transition-system
\[ \forall p : \text{state}, x : \text{action} \quad \text{accepted_actions}(p) = \text{refused_actions}(p). \]

### 3.1 Testing Preorders

In this section we define two partial orderings on the set of all processes. We do this only to relate our approach to the existing theories of acceptance and failure semantics, even though we will not use these concepts explicitly. Indeed, of more interest to us is the concept of testing equivalence which we discuss in the next subsection.

**Definition 3.10 (may_refuse_after)**
Theory: monoid-transition-system
\[ x : \text{sets[action]}, u : U, p : \text{state} \mapsto \\
\exists q : \text{state} \quad \text{conjunction} \\
\quad \bullet p \xrightarrow{u} q \\
\quad \bullet x \subseteq \text{refused_actions}(q) \].

**Definition 3.11 (< may_refuse)**
Theory: monoid-transition-system
\[ p, q : \text{state} \mapsto \\
\forall x : \text{sets[action]}, u : U \quad s. t. \quad \text{may_refuse_after}(x, u, p), \\
\text{may_refuse_after}(x, u, q) \].
The following is one of the key concepts in the testing semantics we are investigating. The significance of this concept will be elucidated below in a series of theorems.

**Definition 3.12 (failures)**
Theory: monoid-transition-system
\[ [p: \text{state} \mapsto [u: U \mapsto \{s: \text{sets[\text{action}] | } \exists q: \text{state } p \xrightarrow{u} q \land s \subseteq \text{refused}\_\text{actions}(q)\}]]. \]

**Theorem 3.13 (failures-characterization-of-\(<\_\text{may}\_\text{refuse}\))**
Theory: monoid-transition-system
\[ \forall p, q: \text{state} \iff \]
\[ \bullet <\text{may}\_\text{refuse}(p, q) \]
\[ \bullet \forall u: U \text{ failures}(p)(u) \subseteq \text{failures}(q)(u). \]

**Definition 3.14 (must\_refuse\_after)**
Theory: monoid-transition-system
\[ [x: \text{sets[\text{action}]}, u: U, p: \text{state} \mapsto \forall q: \text{state } s. t. p \xrightarrow{u} q,
\]
\[ x \subseteq \text{refused}\_\text{actions}(q)]. \]

**Lemma 3.15 (must\_refuse\_after-characterization-lemma)**
Theory: monoid-transition-system
\[ \forall x: \text{sets[\text{action}]}, u: U, p: \text{state} \iff \]
\[ \bullet \text{must}\_\text{refuse}\_\text{after}(x, u, p) \]
\[ \bullet x \subseteq \bigcap \{ [q: \text{state} \mapsto \]
\[ \quad \quad \text{if } p \xrightarrow{u} q \text{ then refused}\_\text{actions}(q) \text{ else sort}\_\text{indicator}(\text{action})] \}. \]

**Definition 3.16 (successors\_after)**
Theory: monoid-transition-system
\[ [p: \text{state} \mapsto [u: U \mapsto \{a: \text{action} | \exists q: \text{state } p \xrightarrow{u} q \land a \in \text{accepted}\_\text{actions}(q)\}]]. \]

**Theorem 3.17 (successors\_after-complement)**
Theory: monoid-transition-system
\[ \forall p: \text{state}, u: U \bigcap \{ [q: \text{state} \mapsto \]
\[ \quad \quad \text{conditionally, if } p \xrightarrow{u} q \]
\[ \quad \quad \bullet \text{then refused}\_\text{actions}(q) \]
\[ \quad \quad \bullet \text{else sort}\_\text{indicator}(\text{action})] \} = \overline{\text{successors}\_\text{after}(p)(u)}. \]
Theorem 3.18 (must_refuse_after-characterization)
Theorem: monoid-transition-system
\[ \forall x : \text{sets}[\text{action}], u : \mathbf{U}, p : \text{state} \iff \\
\quad \bullet \quad \text{must_refuse_after}(x, u, p) \\
\quad \bullet \quad x \subseteq (\text{successors_after}(p)(u)). \]

Definition 3.19 (< must_refuse)
Theorem: monoid-transition-system
\[ [p, q : \text{state} \mapsto \\
\quad \forall x : \text{sets}[\text{action}], u : \mathbf{U} \quad s. \ t. \quad \text{must_refuse_after}(x, u, p), \\
\quad \text{must_refuse_after}(x, u, q)]. \]

Theorem 3.20 (characterization-of-< must_refuse)
Theorem: monoid-transition-system
\[ \forall p, q : \text{state} \iff \\
\quad \bullet \quad <_{\text{must_refuse}}(q, p) \\
\quad \bullet \quad \forall u : \mathbf{U} \quad \text{successors_after}(p)(u) \subseteq \text{successors_after}(q)(u). \]

Definition 3.21 (must_accept_after)
Theorem: monoid-transition-system
\[ [x : \text{sets}[\text{action}], u : \mathbf{U}, p : \text{state} \mapsto \\
\quad \forall q : \text{state} \quad s. \ t. \quad p \xrightarrow{u} q, \\
\quad \neg(x \circ \text{accepted_actions}(q))]. \]

Definition 3.22 (may_accept_after)
Theorem: monoid-transition-system
\[ [x : \text{sets}[\text{action}], u : \mathbf{U}, p : \text{state} \mapsto \\
\quad \exists q : \text{state} \quad \text{conjunction} \\
\quad \bullet \quad p \xrightarrow{u} q \\
\quad \bullet \quad \neg(x \circ \text{accepted_actions}(q))]. \]

Theorem 3.23 (must_accept_after-negation-of-may_refuse_after)
Theorem: monoid-transition-system
\[ \forall p : \text{state}, x : \text{sets}[\text{action}], u : \mathbf{U} \iff \\
\quad \bullet \quad \text{must_accept_after}(x, u, p) \\
\quad \bullet \quad \neg(\text{may_refuse_after}(x, u, p)). \]

Theorem 3.24 (testing-characterization-of-< may_refuse)
Theorem: monoid-transition-system
∀p, q : state \iff
\bullet \, <_{\text{may\_refuse}} (p, q)
\bullet \, \forall x : \text{sets}[\text{action}], u : \text{U} \; s.t. \; \text{must\_accept\_after}(x, u, q),
\text{must\_accept\_after}(x, u, p).

**Theorem 3.25 (may\_accept\_after\_negation-of-must\_refuse\_after)**
Theory: monoid-transition-system
∀p : state, x : sets[\text{action}], u : \text{U} \iff
\bullet \, \text{may\_accept\_after}(x, u, p)
\bullet \, \neg(\text{must\_refuse\_after}(x, u, p)).

**Theorem 3.26 (testing-characterization-of-<\_must\_refuse)**
Theory: monoid-transition-system
∀p, q : state \iff
\bullet \, <_{\text{must\_refuse}} (p, q)
\bullet \, \forall x : \text{sets}[\text{action}], u : \text{U} \; s.t. \; \text{may\_accept\_after}(x, u, q),
\text{may\_accept\_after}(x, u, p).

**Theorem 3.27 (accepted\_transitions-characterization-of-<\_must\_refuse)**
Theory: monoid-transition-system
∀p, q : state \iff
\bullet \, <_{\text{must\_refuse}} (q, p)
\bullet \, \text{accepted\_transitions}(p) \subseteq \text{accepted\_transitions}(q).

### 3.2 Testing Equivalence

To complete this circle of ideas, we introduce a relation on the sort state and prove that the mapping \( p \mapsto \text{failures}(p) \) separates precisely those pairs of points which are inequivalent.

**Definition 3.28 (=\_may\_refuse)**
Theory: monoid-transition-system
\[ p, q : \text{state} \mapsto \]
∀x : \text{sets}[\text{action}], u : \text{U} \iff
\bullet \, \text{may\_refuse\_after}(x, u, p)
\bullet \, \text{may\_refuse\_after}(x, u, q).

**Theorem 3.29 (failures-characterization-of-=\_may\_refuse)**
Theory: graded-monoid-transition-system
∀p, q : state \iff 
- \text{may_refuse}(p, q)
- \text{failures}(p) = \text{failures}(q)

3.3 Failures as Independent Objects

We would like to characterize the image of the mapping which associates to a process its possible failures. Unfortunately, this does not appear to be possible. However, we may restrict the possibilities to some extent. We begin with a useful definition.

**Definition 3.30 (support)**

Theory: directed-monoid-theory

\[ [f : U \rightarrow \text{sets}[\text{sets}[\text{action}]] \rightarrow \{u : U \mid \text{nonempty } \{f(u)\}] \] .

The formal definition of failure which follows comprises six conditions which are suggested by the definition of the classic paper [1]. We will say \( u \) is a trace of the process \( f \), if \( u \in \text{support } f \). A process \( f \) may refuse a set of actions \( y \) after a trace \( u \), if \( y \in f(u) \).

Informally, a function

\[ f : U \rightarrow \text{sets}[\text{sets}[\text{action}]] \]

is a failure if

1. Whenever a process can refuse a set of actions \( y \) after a trace \( u \), then it can refuse any subset of \( y \).
2. \( e \) is always a trace.
3. Any prefix of a trace is a trace.
4. If \( u \) is a trace and \( a \) an action, then either
   - The trace \( u \) has an extension whose germ is \( a \)
   - \( a \) can always be added to any refusal set after \( u \).
5. The function is defined for all transitions.
6. The germ of \( e \) is never refused.

Here then is the formal IMPs definition of failures:
Definition 3.31 (failure_q)
Theory: directed-monoid-theory
\[ f : U \rightarrow \text{sets}[\text{sets}[\text{action}]] \]

\[ \Rightarrow \]

\[
\begin{align*}
\text{conjunction} & \quad \forall u : U, x, y : \text{sets}[\text{action}] \quad (y \in f(u) \land x \subseteq y) \supset x \in f(u) \\
& \quad \forall u, v : U \quad (u \in \text{support}(f) \land \text{prefix}(v, u)) \supset v \in \text{support}(f) \\
& \quad \forall u : U, a : \text{action} \quad u \in \text{support}(f) \supset (\exists m : U \quad \text{germ}(m) = a \land \\
& \quad u \cdot m \in \text{support}(f) \lor \forall x : \text{sets}[\text{action}] \quad x \in f(u) \Rightarrow x \cup \{a\} \in f(u)) \\
& \quad \text{total}(f, [U \rightarrow \text{sets}[\text{sets}[\text{action}]]]) \\
& \quad \forall u : U, s : \text{sets}[\text{action}] \quad s \in f(u) \supset \neg (\text{germ}(e) \in s). 
\end{align*}
\]

Lemma 3.32 (e-is-never-refused)
Theory: monoid-transition-system
\[ \forall p : \text{state} \quad \neg (\text{germ}(e) \in \text{refused}\_\text{actions}(p)). \]

The following theorem is not a characterization of the failures of a set of processes. However, it does say that our abstract definition of failures does include all those that arise as failures of a monoid transition system.

Theorem 3.33 (range-of-failures)
Theory: monoid-transition-system
\[ \forall p : \text{state} \quad \text{failure}_q(\text{failures}(p)). \]

Lemma 3.34 (not-everything-is-a-failure)
Theory: directed-monoid-theory
\[ \neg (\text{failure}_q([x : U \mapsto \emptyset])). \]

Definition 3.35 (stop_ff)
Theory: directed-monoid-theory
\[ [x : U \mapsto \]

\[ \text{conditionally, if } x = e \]

\[ \text{then } \{s : \text{sets}[\text{action}] \mid \neg (\text{germ}(e) \in s)\} \]

\[ \text{else } \emptyset]. \]

Theorem 3.36 (stop-is-a-failure)
Theory: directed-monoid-theory
\[ \text{failure}_q(\text{stop}_F). \]

13
Component theory: directed-monoid-theory

Top level axioms:

divisibility \( \forall a : U \quad \text{s. t.} \quad \neg(a = e), \quad \exists b : U \quad \text{conjunction} \)

- \( \neg(b = e) \)
- \( \operatorname{prefix}(b, a) \)
- \( 0 \leq \operatorname{lngth}(b) \)
- \( \operatorname{lngth}(b) \leq 1. \)

length-non-negative \( \forall a : U \quad 0 \leq \operatorname{lngth}(a). \)

length-of-product \( \forall a, b : U \quad \operatorname{lngth}(a \cdot b) = \operatorname{lngth}(a) + \operatorname{lngth}(b). \)

Figure 4: Components and axioms for graded-monoid

It is convenient to have an atomic sort denoting the set of failures. This is possible by the preceding theorem which states that the set of failures is nonempty. We will denote this sort by \( F \).

**Sort Definition 3.37 (F)**

Theory: directed-monoid-theory

\( \operatorname{lngth}_q \).

### 3.4 Graded Monoids

A graded monoid is a directed monoid with a length function \( \operatorname{lngth} \). The \( "e" \) is deliberately omitted to distinguish the operator from the length function for arbitrary finite sequences. There is an \textsc{imps}-specific technical point we are slurring over here, since “length” is really a quasi-constructor, a kind of abbreviation.

**Language 3.38 (language-for-graded-monoid)**

Embedded language: \textit{directed-monoid-theory}

Constant: \( \operatorname{lngth} : [U \rightarrow R] \)
**Component theories:** graded-monoid monoid-transition-system

**Top level axioms:** There are none.

Figure 5: Components and axioms for graded-monoid-transition-system

**Theory 3.39 (graded-monoid)**

4 The Metric Space of Failures

In the previous section, we have associated to each element \(p\) of a monoid transition system the function \(u \mapsto \text{failures}(q)(u)\) defined on the transition set, that is, the carrier set of the monoid. Moreover, this function is faithful, in that distinguishes any two processes that are observably distinct. In this section, we study more closely the space of failures and show that it has the structure of a complete metric space. In order to do this, we need some results about a class of metric spaces we refer to as tree-like spaces. We postpone discussion of these spaces to the appendices.

There are various other approaches to constructing metric-space models for processes. One approach constructs these models as a fixed point (in a categorical sense) of a certain functor in the category of metric spaces see [2].

We begin with a completely straightforward technical lemma which states the obvious fact that the composed function \(\text{floor} \circ \text{length}\) maps \(\mathbb{U}\) into \(\mathbb{N}\).

Theorem 4.1 (Anonymous-11)
Theory: graded-monoid
\(\text{floor} \circ \text{length} \downarrow \left[\mathbb{U} \rightarrow \mathbb{N}\right]\).

We now apply the general theory of functions on a graded set. This theory is developed in the appendices. In the application, the underlying set is just the carrier set of the monoid, and the grading function is the floor of the length.

Translation 4.2 (functions-on-a-graded-set-to-graded-monoid)
Source Theory: functions-on-a-graded-set
Target Theory: graded-monoid
Sort Pairs: values \(\mapsto\) sets[sets[action]]
Constant Pairs: degree \(\mapsto\) floor \(\circ\) length
This translation is a theory interpretation.
Theorem 4.3 (Anonymous-12)
Theorem: graded-monoid

Translation 4.6 (degree-equivalence-to-graded-monoid)
Source Theory: degree-equivalence
Target Theory: graded-monoid
Sort Pairs: \( P \mapsto \text{total}_\text{fns} \)
Constant Pairs: approx \( \mapsto \text{fn}_{\text{approx}} \)
This translation is a theory interpretation.

Theorem 4.7 (characterization-ultrametric-limit-of-fns)
Theory: graded-monoid
\( \forall f : \mathbb{Z} \rightarrow \text{total}_\text{fns}, s : \text{total}_\text{fns} \quad \iff \)
\( \bullet \ \lim f = s \)
\( \bullet \ \forall m : \mathbb{Z} \ s. t. \ 0 \leq m, \)
\( \exists n : \mathbb{Z} \ \forall p : \mathbb{Z}, u : \mathbb{U} \ s. t. \ n \leq p \land \text{length}(u) < m + 1, \)
\( f(p)(u) = s(u). \)

Lemma 4.8 (prefix-has-smaller-length-lemma)
Theory: graded-monoid
\( \forall a, b : \mathbb{U} \ s. t. \ \text{prefix}(a, b), \)
\( \text{length}(a) \leq \text{length}(b). \)
Theorem 4.9 (failure\_q\text{-is-closed-under-lim})
Theory: graded-monoid
\(\forall s : \mathbb{Z} \rightarrow \text{total\_fns} \quad \text{implication}\)
- conjunction
  - \(\lim s \downarrow\)
  - \(\forall n : \mathbb{Z} \quad s(n) \downarrow \supset \text{failure}_q(s(n))\)
- \(\text{failure}_q(\lim s)\).

The following is the basic result which allows recursive definitions of processes. Recall that a metric space is complete if and only every Cauchy sequence in it converges. In the following theorem, the constant \text{sub\_complete} is an element of sort \text{prop}. Its meaning is that the set of elements in \(F\), in the metric induced from the space of all functions

\[U \rightarrow \text{sets[sets[action]]}\]

is complete. Notice that in informal parlance one would have just said \(F\) is complete, but such distinctions are one of the burdens of formal mathematics.

Theorem 4.10 (completeness-of-ff)
Theory: graded-monoid
\text{sub\_complete}.
Component theory:  h-o-real-arithmetic
Top level axioms:

approx-separation \( \forall x, y : P \ \text{s. t. } \neg(x = y), \exists n : \mathbb{Z} \ \neg(\text{approx}(x, y, n)) \).

approx-monotonicity \( \forall m, n : \mathbb{Z}, x, y : P \ \text{s. t. } \text{approx}(x, y, n) \land m \leq n, \text{approx}(x, y, m) \).

approx-existence \( \forall x, y : P \ \exists m : \mathbb{Z} \ \text{approx}(x, y, m) \).

approx-reflexivity \( \forall m : \mathbb{Z}, x : P \ \text{approx}(x, x, m) \).

approx-symmetry \( \forall m : \mathbb{Z}, x, y : P \ \text{s. t. } \text{approx}(x, y, m), \text{approx}(y, x, m) \).

approx-transitivity \( \forall m : \mathbb{Z}, x, y, z : P \ \text{s. t. } \text{approx}(x, y, m) \land \text{approx}(y, z, m), \text{approx}(x, z, m) \).

Figure 6: Components and axioms for degree-equivalence

A Tree-like Metric Spaces

In this section we discuss sets \( P \) which are tree-like in the following sense:
for each integer \( n \), there is a relation of equality of degree \( n \) on the set \( P \). Of course, we assume this relation satisfies some natural equivalence properties.
The set of paths through a labelled tree form a natural example of such a structure. In this case, we say paths \( p, p' \) are equal of order \( n \) if they coincide up to the step \( n \).

In this section we assume basic facts about metric spaces.

Theorem C.6 (condition-for-contractions-on-function-spaces)
Theory: mappings-into-a-pointed-metric-space
\( \forall f : \text{bfun} \rightarrow \text{bfun} \) implication
- \( \exists k : \mathbb{R} \) conjunction
  - \( 0 < k \)
  - \( k < 1 \)
  - \( \forall \phi, \psi : \text{bfun}, x : \text{ind}_1 \exists y : \text{ind}_1 \ dist(f(\phi)(x), f(\psi)(x)) \leq k \cdot dist(\phi(y), \psi(y)) \)
- contraction\((f)\).
